[Please insert professional letterhead and date of signature in MM/DD/YYYY format]

To the Adjudicating Officer,

In my capacity as a professor at the University of California, Berkeley, I, Dr. Xiaoting Wong, have had substantial professional engagement with Dr. Moyi Chen. Specifically, through our shared time at the University of California, Berkeley, we have collaborated on research projects in implantable sensors, MRI (magnetic resonance imaging)-compatible devices, and wireless biomedical systems. Through our interactions, I have had the opportunity to observe Dr. Chen's capabilities firsthand. Additionally, I have developed a strong sense of Dr. Chen's research interests and proposed endeavor, which centers on designing multimodal diagnostic and therapeutic platforms that integrate patient-specific physiological signal monitoring to advance clinical decision-making and biomedical technology. Please accept this letter as verification of Dr. Chen's pursuit of her proposed endeavor and our ongoing research project. I must also note that Dr. Chen's proposed endeavor, and by extension our collaboration, is vital to the US because it solves the growing clinical and economic burden exerted by chronic diseases nationwide.

To elaborate on the project, Dr. Chen is developing wireless multi-sensor implant networks for MRI-guided monitoring of physiological signals in disease. This project builds upon her prior development of fully wireless, MR-compatible implantable devices and expands them into coordinated networks equipped with diverse sensors. The project supports her proposed endeavor by enabling continuous, patient-specific physiological data acquisition across multiple anatomical sites to support individualized clinical decision-making. Dr. Chen is performing this research at the University of California, Berkeley, with funding support from the National Institutes of Health. This research addresses issues related to chronic disease monitoring, early intervention, and the reduction of hospitalizations across high-burden patient populations.

Furthermore, Dr. Chen's research addresses healthcare challenges currently facing the US. Chronic diseases such as cancer and pulmonary hypertension lack effective tools for continuous monitoring of disease microenvironments and vascular health, resulting in delayed intervention and poorer outcomes. These limitations contribute to high morbidity, mortality, and escalating healthcare expenditures across the nation. Dr. Chen's work introduces wireless, multi-site implantable sensor networks that provide continuous, high-resolution physiological data during MRI procedures and routine care. This capability strengthens emergency and critical care by enabling seamless monitoring without reliance on bulky, wired hospital-based systems. Additionally, the real-time datasets generated by these implant networks support data-driven healthcare and artificial intelligence integration, supporting national efforts to modernize clinical decision-making and biomedical infrastructure.

In conclusion, Dr. Chen's expertise in electrical and computer engineering makes her an excellent researcher to pursue wireless multi-sensor implant networks for MRI-guided physiological monitoring, which is central to her proposed endeavor and directly aligned with our collaborative work. This research supports national efforts to improve chronic disease management, strengthen critical care capabilities, and maintain US leadership in biomedical innovation. I am enthusiastic to continue our work on this project and build on Dr. Chen's

current progress toward personalized medicine, clinical decision-making, and healthcare innovation.

Respectfully yours,
